## Forage Yields from

# 2010-2011 Ryegrass Variety Trial

by Jagadeesh Mosali

NF-FO-11-02

### Introduction

Livestock and forage production are the largest contributors to agricultural income in the primary service region of the Noble Foundation. The ryegrass (*Lolium multiflorum* L) variety testing program is designed to provide up-to-date performance information to cooperators and producers in Oklahoma and Texas on ryegrass varieties that are commercially and commonly available. In addition, the program provides a tool to evaluate and compare experimental breeding lines emerging from the Noble Foundation breeding program as well as other public and private breeding programs.

This program is intended to furnish cooperators and producers with supplemental information and to aid decision-making and idea formation. The information coming from the variety testing program should be a valuable tool when used with similar information from other sources. The objective of this report is to summarize forage yield from the 2010-2011 ryegrass variety trial.

### Materials and Methods

The annual ryegrass variety trial was conducted on a Wilson silt loam soil at the Noble Foundation Headquarters Farm, Ardmore, Okla. The experimental design is a randomized complete block with three replications. The experimental unit is a 5- by 10-foot plot of a single variety. The trial consisted of 36 entries that were evaluated during the 2010-2011 crop growing season. Ten sources contributed entries to the trial (Table 1).

The entries were seeded in a clean-tilled seedbed on Sept. 17, 2010. Each entry was drilled in 5- by 10-foot plots, in 7-inch rows, at 25 lbs/ac (pure live seed basis) at a ½-inch planting depth with a HEGE 500 drill. The experimental area was sprayed for aphids with Cobalt @13 oz/ac on Sept. 30, 2010. Fertilization consisted of pre-plant incorporation of 50 lbs K2O/ac on Sept. 16, 2010. Nitrogen fertilizer was applied at 60 lbs N/ac on Oct. 21, 2010, and a topdress application of 75 lbs N/acre on Feb. 23, 2011. Plots were harvested with a HEGE sickle bar forage plot harvester at a 3-inch height on Nov. 20, ►

2010; Feb. 22, March 10, April 14 and May 17, 2011. Data was analyzed with the general linear models procedure in SAS (Statistical Analysis Software, Cary, N.C.), and means were separated by the least significant difference (LSD) method ( $P \leq 0.05$ ).

## Results and Discussion

Average growing conditions are reported in Table 2. The seasonal rainfall total is less than the 30-year average. The monthly rainfall total is very low in the months of March and April compared to the 30-year average and contributed to lower yields in those months. Due to better moisture conditions in May, forage yields were higher. Overall, forage yields depended on the ryegrass variety and harvest date. Forage yields are reported in Table 3. Dry matter forage yields for ryegrass cultivars and strains ranged from 17 lbs/ac to 2,031; 935 lbs/ac to 4,145 lbs/ac; 470 lbs/ac to 1,391 lbs/ac; 403 lbs/ac to 2,051 lbs/ac; and 932 lbs/ac to 4,208 lbs/ac during November, February, March, April and May harvest periods, respectively, and the total forage yield was between 3,018 lbs/ac and 11,805 lbs/ac (Table 3). There was no significant difference in forage yields among Passerel Plus, TAMTO, DH3, ME-94 Experimental, Terastar(4), Jackson, B-10.141 AR(2), Winterhawk, Tam 90, Big Boss, Jumbo, Lonestar and Fria which have yielded more than 9,000 lbs/ac. There were no significant forage yield differences among the rest of the varieties in the trial. The total forage yields are better in the 2010-2011 crop growing season compared to the year before due to better rainfall conditions than the previous year during early fall and in late April to early May. ●

## Acknowledgments

Shawn Norton, Julie Barrick, Roger Hartwell, Kevin Lynch and Derick Warren assisted with the establishment, maintenance, harvesting and data collection of this trial.
